

REMARKS

The present amendment makes editorial changes and corrects typographical errors in the specification, which includes the Abstract, in order to conform the specification to the requirements of United States Patent Practice. No new matter is added thereby. Attached hereto is a Substitute Specification including a marked-up version of the changes made thereto via by the present amendment.

In addition, the present amendment cancels original claims 1-12 in favor of new claims 13-23. Claims 13-23 have been presented solely because the revisions by red-lining and underlining which would have been necessary in claims 1-12 in order to present those claims in accordance with preferred United States Patent Practice would have been too extensive, and thus would have been too burdensome. The present amendment is intended for clarification purposes only and not for substantial reasons related to patentability pursuant to 35 U.S.C. §§101, 102, 103 or 112. Indeed, the cancellation of claims 1-12 does not constitute an intent on the part of the Applicants to surrender any of the subject matter of claims 1-12.

Early consideration on the merits is respectfully requested.

Respectfully submitted,

William E. Vaughan

Description

Method and system for transmitting data packets

The present invention relates to a method and a system for transmitting data
5 packets.

SPECIFICATION

TITLE OF THE INVENTION

METHOD AND SYSTEM FOR TRANSMITTING DATA PACKETS

BACKGROUND OF THE INVENTION

10 Methods~~Such methods~~ and systems for transmitting data packets are used,
for example,~~example~~ used in mobile radio networks.

With many services and applications provided in modern mobile radio
networks,~~networks~~ messages have to be transmitted not to just one but to two or
more mobile radio users. Examples of such services and applications are news
groups, video conferences, video on demand and distributed applications.

15 When transmitting messages to the various users it is possible to send each
recipient a copy of the data separately. Such a method can be
implemented,~~implemented~~ but is unsuitable,~~unsuitable~~ for large groups. As the
same message is transmitted via N (N = number of recipients of the message)
individual connections (unicast connections) and is thereby sent a number~~plurality~~
20 of times via common connection paths, this method requires a very high bandwidth.

So-called multicast transmission is a better option. Here the various users,
to whom the same message is to be transmitted, are combined in a group (multicast
group) and only one address (multicast address) is assigned to such~~said~~ group. The
data to be transmitted is then sent only once to this multicast address. The multicast
25 messages are ideally sent only once via common connection paths from the sender
to the recipients. The sender does not have to know where and how many
recipients are concealed behind the multicast address. In order to receive the
messages of a specific multicast group, a user must register with the~~said~~ multicast
group.

30 During transmission,~~transmission~~ messages are sent to a group of users
within a regional area. The area in which the message is transmitted is referred to

as the broadcast area. The size of the broadcast area is determined by the network operator. ~~Ideally, the~~The message is thereby ~~ideally~~sent only once as with multicast via common connection paths. It is, ~~however, however~~ a disadvantage here that all users within the broadcast area are able to read broadcast messages. In order to read only specific messages and reject or filter others, users can make corresponding adjustments at their terminals. Specific registration for a broadcast service is not necessary.

Users only want to pay for a service if they have actually received the messages of ~~such~~said service. If certain data does not arrive at the mobile radio terminal due to transmission problems, the user cannot be billed for this. A message service such as multicast or broadcast ~~must~~therefore must be sufficiently reliable. Such a reliability requirement ~~can, can~~ for ~~example, example~~ be guaranteed in that users who have not received certain data send corresponding non-receipt information back to the network and then the "lost" data of the message is transmitted to ~~such~~said users again. One problem here is that such a multi-transmission, in order to guarantee the receipt of data, requires a high outlay, in particular as this data is sent to an entire group of users ~~again; again,~~ in other ~~words, words~~ even to ~~users~~said users, who have already received the data correctly. The advantage achieved with multicast or broadcast with regard to transmission capacity savings is lost as a result. Also with known systems it is not possible to charge for a service such as broadcast or multicast, as the data is sent unconfirmed from the sender to the recipient. As far as future chargeable services are ~~concerned, concerned~~ however, users only want to pay for data that they have actually received.

The ~~object of the~~ present invention is, ~~therefore, therefore~~ directed towardto provide a method and system for transmitting data ~~packets~~packets, with which reliable charging is ensured with little network loading.

~~A method and a system for transmitting data packets according to the independent Claims are proposed to achieve said object. Further advantageous embodiments are set out in the subclaims.~~

SUMMARY OF THE INVENTION

The inventive method for transmitting data packets has the following method stages: a data packet is sent from a sender to a recipient and a confirmation message confirming receipt of the data packet is sent from the recipient to the sender. When sending the data ~~packet, packet~~ a timer for monitoring receipt of the confirmation message is started.

The present invention is preferably used in a third generation mobile radio ~~network; e.g., network, e.g.~~ UMTS (Universal Mobile Telecommunications System). In such a ~~system, system~~ the sender is, ~~for example, for example~~ a UMTS base station connected to a network and the recipient is a UMTS mobile radio terminal. The present invention can, ~~however, however in principle~~ be used for any type of transmission system. The data packets and confirmation message can, ~~in principle, in principle~~ be sent on the basis of any mobile radio standard. The timer determines the time period between the time when the data packet is sent and acknowledgment via a confirmation message returns to the sender within a predefined time interval.

In one ~~a preferred~~ embodiment of the present ~~invention, invention~~ no more data packets are sent from the sender to the recipient if no confirmation message reaches the sender within a time frame started by the timer. In such a ~~case, case~~ it can be assumed that the data packets ~~have either~~ have not reached the recipient or the recipient ~~is, is in principle, principle~~ not sending confirmation messages back to the sender.

In a development of the present ~~invention, invention~~ data packets are not charged ~~for for~~, if no confirmation message reaches the sender within a time frame started by the timer. Users of the recipient, receiving data packets from the sender, only want to pay a charge for the receipt of data packets, if the data packet has not only been sent by the sender but they have also actually received it. It is possible for a sender to have sent a data packet but for this not to have reached the recipient, ~~for example, for example~~ due to radio holes. In such a ~~case, case~~ it is obvious that the user of the recipient will not want to pay charges for the unused data packet. ~~Therefore, In such a case therefore~~ charging does not take place.

In a further development of the present ~~invention, invention~~ a status request is sent from the sender to the ~~recipient~~ recipient, if no confirmation message reaches the sender within a time frame started by the timer. Such a status request can be used to verify the status of the recipient. If, for example, ~~for example~~ the recipient is no longer able to send confirmation messages to the sender, this can be determined via ~~by means of~~ the status request. It is also possible for the user terminal to have been manipulated so that it no longer sends confirmation messages. No proof is therefore provided of the fact that the data packet has actually reached the terminal. In such a case, ~~case~~ it can be verified via ~~by means of~~ the status request whether any manipulation is taking place.

According to the ~~present invention, invention~~ on receipt of a confirmation message the sender resets the timer and the data packet is charged for. This is the normal scenario. On receipt of the confirmation message the timer is reset and started again when a new data packet is sent. As there is proof that the recipient has received the data packet correctly, the data packet can then be charged for.

In yet another development of the present invention, if a data packet is not correctly received and/or is not received, a non-receipt message is sent from the recipient to the sender. If a data packet is not received correctly, that is, i.e. if a data packet was not received in full or only partially by the recipient, it is possible for a non-receipt message to be sent to the sender. In such a case charging does not take place. It is also possible, however, for the data packet that was not transmitted correctly to be sent again. It is however also possible, if no data packet was received by the recipient, for a non-receipt message to be sent similarly from the recipient to the sender. In this case, too, ~~too~~ charging does not take place or the data packet not received is sent again.

According to the ~~present invention, invention~~ the number of non-receipt messages received is stored in the storage unit. The number of non-receipt messages received is a measure of the data packets not transmitted correctly. Should too many data packets not be transmitted correctly, it must be verified on the part of the sender whether there is a fundamental problem or whether manipulation is taking place at the recipient. To this end, ~~according to the~~

~~invention~~ if a limit value for non-receipt messages received is exceeded, a status request is sent from the sender to the recipient. This status request can, in turn, ~~in turn~~ be used to verify whether a number of non-receipt messages higher than the predefined limit value has been sent to the sender.

5 The above-mentioned ~~method~~object is also achieved ~~viaby means of~~ a system for transmitting data packets with ~~partsmeans~~ for sending a data packet from a sender to a recipient and ~~partsmeans~~ for sending a confirmation message confirming receipt of the data packet from the recipient to the sender, with a timer for monitoring receipt of the confirmation message being started when the data
10 packet is sent.

 The present invention also relates to a terminal for use in ~~thean~~ inventive method and a terminal for use in ~~thean~~ inventive system. The terminal is preferably a mobile radio terminal.

 According to the ~~present invention~~invention the recipient sends receipt
15 confirmation to the network on receipt of data packets. In this ~~way~~way the sender is informed of the correct receipt of the data by the recipient. The recipient is then charged accordingly. The receipt confirmation is preferably also sent back to the network on receipt of a set of data packets that belong together, as it may not be possible to decrypt an incomplete data set and it therefore has no value for the user.

20 Advantages result with the present invention in that it is still possible to transmit useful data efficiently using resources and channels common to all the recipients. Regardless of ~~this~~this the confirmation information can be transmitted back to the sender either via recipient-specific or common channels. The use of recipient-specific channels is thereby particularly advantageous as it is possible
25 ~~ideally~~ to use only one bit for the confirmation information (1 = received, 0 = not received).

 On receipt of a receipt confirmation, ~~the~~the sender knows that the data has been received by the users. Users ~~ean~~ then can be charged for the service accordingly. If the sender does not receive a receipt confirmation, the transmitted
30 data of the service is not charged to the user. It ~~must~~ thereby must be ensured that a recipient cannot be manipulated so that it never sends receipt confirmation, as the

user could then receive the service free of charge. In certain conditions, therefore, ~~therefore~~ a request can be sent concerning the status of the recipient to establish why no further receipt information is reaching the sender.

In this ~~context, context~~ it is ~~desirable~~ expedient for a recipient to send a confirmation message back to the sender in the event of correct receipt and to send a non-receipt message back to the sender in the event of incorrect receipt. This non-receipt message then ~~ensures~~ means that the data is not charged to the user. It ~~must~~ thereby must be ensured that a recipient does not always send non-receipt messages back to the sender so that the user can receive the service free of charge.

10 To this end, therefore, ~~therefore~~ in certain conditions a request can be sent concerning the status of the ~~recipient~~ recipient, asking why only non-receipt messages are being sent out by the recipient.

Additional features and advantages of the present invention are described in, and will be apparent from, the following Detailed Description of the Invention and

15 the Figures.

~~The invention is described in more detail below with reference to the accompanying drawings using exemplary embodiments. The features shown there and the features described above can be essential to the invention not only in the specified combination but also individually or in other combinations.~~

20 BRIEF DESCRIPTION OF THE FIGURES

Figure 1a shows a flow diagram of a correct process for the transmission of a data ~~packet~~ packet;

Figure 1b shows a flow diagram of the incorrect transmission of a data packet, ~~and~~

25 Figure 2 shows an exemplary embodiment of the transmission of a ~~number~~ plurality of data packets in a time frame.

DETAILED DESCRIPTION OF THE INVENTION

Figure 1 shows the correct transmission of a data packet P3 from a sender S to a recipient E. When the data packet P3 is sent at time ~~t1, t1~~ a timer is started in the sender S. The receiver E receives the data packet P3 as shown by the arrow 1.

30 On ~~receipt~~ receipt the recipient E sends a confirmation message 2 to the sender S,

which reaches the sender S at time t_x . Time t_x is before the end of the time frame t_2 started by the timer, ~~thesaid~~ time frame being defined by the time t_1 ; ~~i.e., t_1 , i.e.~~ the time when the data packet P3 is sent.

Figure 1b shows the incorrect transmission of a data packet P3 from a sender S to a recipient E. At time t_1 , ~~i.e.~~ the time when the data packet P3 is sent by the sender S, a timer is again started in the sender S, the time frame of which ends at time t_2 . A transmission error 3 occurs during transmission. No confirmation message is therefore sent from the recipient E to the sender S.

Figure 2 shows the transmission of a series of data packets from a sender S to a recipient E. For the exemplary embodiment shown in Figure 2, it is assumed that a message ~~including~~comprising the data packets P1 to P10 is transmitted to a group of recipients via broadcast or multicast. The data is thereby transmitted via channels (resources) common to all recipients. Dedicated or common channels are used to send the confirmation and non-confirmation information back to the network. For the sake of simplicity, in the exemplary embodiment shown in Figure 3, ~~only~~only the sender S and one recipient E are considered. ~~However,~~However the details apply equally to each of the individual recipients of the same message.

The sender S starts to transmit the data packets 1 to 10 and sends them one after ~~another~~the other to the recipient(s). For ~~example,~~example the data packet P3 is sent, as shown by the arrow 10, from the sender S to the recipient E. On receipt of the data packet 10 by the recipient E, the latter confirms receipt by sending a confirmation message 11 to the sender S.

As each individual data packet is sent, a timer (not shown) is started, with the confirmation information being expected before its expiry. If during this period, ~~or i.e.~~ before expiry of the time period defined by the timer, confirmation is received back from the recipient E, the timer is stopped and transmission of the data is charged for accordingly. If the recipient E does not send a confirmation message before expiry of the timer, the data is not charged to the user.

~~If,~~If in the event of ~~non-receipt,~~non-receipt a recipient does not send confirmation back to the sender, ~~i.e.~~ (i.e., the network, to prevent possible manipulation of a recipient so that ~~thesaid~~ recipient never sends confirmation

messages back to the ~~sender~~ sender, it is possible to set up a so-called send window on the network side. Such a window must be managed for each recipient in the sender. Provision of a send window ~~ensures~~ means that data is only transmitted to a recipient until the end of the send window. According to the present invention, ~~invention~~ a request ~~can~~ then can be sent concerning the status of the recipient, whereby it is asked why no confirmation messages are being sent.

In the exemplary embodiment shown in Figure 2, the size of the send window is $n = 4$. The sender S has to send the data packets P1 to P10 to the recipient E. When the data packet P3 has been sent, ~~for example, for example~~ the sender S receives a confirmation message and the send window is then “moved on” so that it starts at the data packet P4 and ends at the data packet P7. If, ~~after~~ after sending the packet ~~P4, P4~~ the sender S receives no confirmation message, the send window is not moved on. The start of the send window remains at the data packet P4.

With a window size of $n = 4$, the data packets P5, P6 and P7 are then transmitted, even if no confirmation messages are sent to the recipient E. After transmission of the data packet P7 and assuming that no further confirmation message has been transmitted, the end of the send window is reached.

As described ~~above~~, ~~above~~ a timer is started after the data packet P7 is sent. Once this timer has expired and when the end of the send window has been reached, a request is sent concerning the status of the recipient E. It is thereby asked why no confirmation messages have been sent. It is possible that the recipient is in a radio hole or cannot be reached for other reasons. In such a ~~case~~, ~~case~~ they should no longer be charged for the service. The send window ~~can~~ then can be moved on again until the start of the window is at the last data packet sent.

If, ~~however~~, ~~however~~ the recipient E has been manipulated so that in principle it never sends ~~confirmation~~ ~~confirmation~~ messages, this can be determined using the request sent, whereby the user is then divested of the right to receive messages. This can be ~~done~~, ~~done~~ for ~~example~~, ~~example~~ ~~throughby means of~~

exclusion from the recipient group initiated by the network or, for example, ~~for example~~ by withdrawing the key for encrypting messages.

5 If the sender S, however, ~~however~~ receives a confirmation message before expiry of the timer, the timer is reset, the send window is moved on (by one position) and the next data packet (P8) can be transmitted. In this case, ~~case~~ no request is sent concerning the status of the terminal.

If confirmation messages are now duly received for all subsequent packets, the send window can be moved on until the start of the window is at the packet currently being sent.

10 If a recipient E only sends non-receipt messages back to the sender S, to prevent manipulation of a recipient E so that it only sends non-receipt messages back to the sender S, a counter can be set up in the sender to count the number of successive non-receipt messages. Such a counter is then managed in the sender S for each recipient.

15 Using such a counter ensures ~~means~~ that data is only transmitted to a recipient E until a predefined value is reached. A request concerning the status of the recipient E ~~can then~~ can be sent from the sender S to the recipient E, whereby it is verified why only non-receipt messages are being sent from the receiver E to the sender S.

20 In principle, ~~principle~~ the mode of operation is ~~thereby~~ similar to the send window method described above but now the number of successive non-receipt messages is counted and a request concerning the status of the terminal E is then sent at a predefined discretionary counter reading. In such a case, ~~case~~ it is again possible that the recipient is in a radio hole or that the data transmission is not possible for other reasons. In such a case, ~~case~~ the recipient should no longer be charged for the service. The counter ~~can then~~ can be reset to zero.

25 However, ~~However~~ should the recipient be manipulated so that it only sends non-receipt messages, this can be determined viably ~~means of~~ the request sent. The user ~~can then~~ can be divested of the right to receive messages. This ~~can again~~ can
30 be done by exclusion from the recipient group initiated by the network or by withdrawing the key for encrypting the messages.

If the sender S, however, ~~however~~ receives a confirmation message before expiry of the timer, the counter is not incremented further and the next data packet can be transmitted. No request concerning the status of the recipient E is thereby sent. If correct confirmation messages are subsequently received for all packets,
5 the counter is reset to zero.

Although the present invention has been described with reference to specific embodiments, those of skill in the art will recognize that changes may be made thereto without departing from the spirit and scope of the present invention as set forth in the hereafter appended claims.

ABSTRACT OF THE DISCLOSURE

~~The invention relates to a~~ A method is provided for transmitting data packets, which includes comprising the following methods: sending a data packet from a sender (S) to a recipient (E), and; sending a confirmation message from
5 recipient (E) to sender (S) in order to confirm the receipt of the data packet. When sending the data packet, a timer for monitoring the receipt of the confirmation message is started. According to the present invention, no charges for the transmission of the data packet are assessed when no confirmation message from the recipient (E) arrives within a time frame initiated by the timer.

10
